 Title: The logarithmic chain complex  
 Slide Nr. 1/8

The conventional sum,  $+$ , and multiplication,  $\times$ , are abelian products with distributivity. For example, if,  $\alpha, \beta, \gamma \in (\mathbb{R}, +, \times)$ , then,

$$\alpha \times (\beta + \gamma) = \alpha \times \beta + \alpha \times \gamma. \quad (1)$$

Formally, these two products form a *ring*. As aspiring goldsmiths we shall try to make chains out of these rings. Let,  $\overset{0}{\times}$ , and,  $\overset{1}{\times}$ , denote two products that behave like the conventional sum and multiplication, respectively. The set of products<sup>1</sup>,  $n \in \mathbb{Z}$ :

$$\alpha \overset{n+1}{\times} \beta \doteq \log^{-1} \left( \log(\alpha) \overset{n}{\times} \log(\beta) \right), \quad (2)$$

form a sequence of abelian groups and homomorphisms. Note that,  $\overset{n+1}{\times}$ , is distributive in,  $\overset{n}{\times}$ . Proof by induction: Assume,

$$\alpha \overset{n}{\times} (\beta \overset{n-1}{\times} \gamma) = (\alpha \overset{n}{\times} \beta) \overset{n-1}{\times} (\alpha \overset{n}{\times} \gamma), \quad (3)$$

then,

$$\begin{aligned} \alpha \overset{n+1}{\times} (\beta \overset{n}{\times} \gamma) &= \log^{-1} \{ \log(\alpha) \overset{n}{\times} \log(\beta \overset{n}{\times} \gamma) \} \\ &= \log^{-1} \{ \log(\alpha) \overset{n}{\times} [\log(\beta) \overset{n-1}{\times} \log(\gamma)] \} \\ &\stackrel{(3)}{=} \log^{-1} \{ [\log(\alpha) \overset{n}{\times} \log(\beta)] \overset{n-1}{\times} [\log(\alpha) \overset{n}{\times} \log(\gamma)] \} \\ &= \log^{-1} \{ \log(\alpha \overset{n+1}{\times} \beta) \overset{n-1}{\times} \log(\alpha \overset{n+1}{\times} \gamma) \} \\ &= (\alpha \overset{n+1}{\times} \beta) \overset{n}{\times} (\alpha \overset{n+1}{\times} \gamma). \end{aligned} \quad (4)$$

This covers the proof for,  $n \in \mathbb{Z}^+$ . Left to the reader is the proof for,  $n \in \mathbb{Z}^-$ .

In future posts, I will share more trivia about this structure and discuss possible applications.

---

<sup>1</sup>Details such as the base of the log function and its algebraic role are discussed later on.

 Title: The logarithmic chain complex  
 Slide Nr. 2/8

In the latest slide we defined a sequence of abelian products, based on the log function. A complete definition requires a generalisation of the log function to operate on negative reals. Before doing this, let us appreciate the behaviour of these products in,  $\mathbb{R}^+$ . The definition in Eq. (2) makes it clear these products are commutative. As observed in Coya's law, this is not always obvious, e.g., the equivalent definition of,  $\overset{2}{\times}$ , as,

$$\alpha \overset{2}{\times} \beta = \alpha^{\log \beta}. \quad (5)$$

The product,  $\overset{2}{\times}$ , is interesting, together with,  $\overset{-1}{\times}$ , are the closest relatives to the conventional products,  $\overset{0}{\times}$ , and,  $\overset{1}{\times}$ , for which we hold more intuition. The product,  $\overset{2}{\times}$ , is distributive in the conventional multiplication ( $\overset{1}{\times}$ ). This makes,  $\overset{2}{\times}$ , the abelian version of the power product, which is also distributive in the multiplication, i.e.,  $(\alpha \times \beta)^\gamma = \alpha^\gamma \times \beta^\gamma$ .

It is convenient to move to a more abstract characterisation. Each product,  $\overset{n}{\times}$ , forms a group denoted,  $\mathfrak{g}_n$ , with elements,  $\overset{n}{\alpha}, \overset{n}{\beta}, \dots$ . Arbitrary elements in the sequence of groups are denoted without the upper index, i.e.,  $\alpha$ . Some definitions and conventions:

$$\overset{n}{\alpha} \overset{n}{\times} \overset{n}{\beta} = \overset{n}{\beta} \overset{n}{\times} \overset{n}{\alpha}, \quad (6a)$$

$$\overset{n}{\alpha} \overset{n}{\times} \overset{n}{I}_0 = \overset{n}{I}_0 \overset{n}{\times} \overset{n}{\alpha} = \overset{n}{\alpha}, \quad (6b)$$

$$\overset{n}{\alpha} \overset{n}{\times} \overset{n}{I}_1 = \overset{n}{I}_1 \overset{n}{\times} \overset{n}{\alpha} = \overset{n}{I}_1. \quad (6c)$$

$$(\overset{n}{\mathcal{F}}(\overset{n}{\mathcal{F}}\overset{n}{\alpha})) = \overset{n}{\alpha} \quad (7a)$$

$$\overset{n}{\alpha} \overset{n}{\times} (\overset{n}{\mathcal{F}}\overset{n}{\alpha}) = (\overset{n}{\mathcal{F}}\overset{n}{\alpha}) \overset{n}{\times} \overset{n}{\alpha} = \overset{n}{I}_0, \quad (7b)$$

$$\overset{n}{\mathcal{F}}\overset{n}{I}_0 = \overset{n}{I}_0 \quad (7c)$$

$$\overset{n}{\alpha} \overset{n}{\times} (\overset{n}{\mathcal{F}}\overset{n}{I}_1) = (\overset{n}{\mathcal{F}}\overset{n}{I}_1) \overset{n}{\times} \overset{n}{\alpha} = \overset{n}{\mathcal{F}}\overset{n}{I}_1. \quad (7d)$$

Abusing of notation on behalf of intuition we keep,  $\log(\cdot)$ , to denote the generator of homomorphisms. We use,  $\log^{+1}(\cdot) = \log(\cdot)$ , and,  $\log^{-1}(\log(\overset{n}{\alpha})) = \log(\log^{-1}(\overset{n}{\alpha})) = \overset{n}{\alpha}$ . The logarithm (and its inverse) connects nearby groups along the sequence, i.e.,

$$\overset{n-1}{\alpha} = \log(\overset{n}{\alpha}) \in \overset{n}{\mathcal{F}}\overset{n}{I}_1 \quad (8a)$$

$$\overset{n+1}{\alpha} = \log^{-1}(\overset{n}{\alpha}) \in \overset{n}{I}_1. \quad (8b)$$

I imagine the elements,  $\overset{n}{\alpha}, \overset{n+1}{\alpha}, \dots$ , as different scales of a physical degree of freedom. Formally,  $\overset{n}{\mathcal{F}}\overset{n}{I}_1$ , and,  $\overset{n}{I}_1$ , are elements of an *ideal*, but they feel as the horizon of too large/small elements from the perspective of the  $n$ -scale. Next we identify these elements in,  $(\mathbb{R}^+, \times)$ .

Twitter thread by @judijasa  
 Title: The logarithmic chain complex  
 Slide Nr. 3/8

As a complement to Eqs. (8) are the relations,

$$\log(\overset{n}{\mathcal{F}} \overset{n}{I}_1) = \overset{n-1}{\mathcal{F}} \overset{n-1}{I}_1, \quad \log(\overset{n}{I}_1) = \overset{n-1}{I}_1, \quad \text{and}, \quad \log(\overset{n}{I}_0) = \overset{n-1}{I}_0. \quad (9)$$

*Example.* Taking,  $(\mathbb{R}^+, \times)$ , as a representation of the  $n$ -group  $(\mathfrak{g}_n)$  one obtains that,

$$0^+ \equiv \overset{n}{\mathcal{F}} \overset{n}{I}_1, \quad +\infty \equiv \overset{n}{I}_1, \quad 1 \equiv \overset{n}{I}_0, \quad \text{and}, \quad 1/\overset{n}{\alpha} \equiv \overset{n}{\mathcal{F}} \overset{n}{\alpha}. \quad (10)$$

Denoting,  $\log[y](x) = \log_y(x)$ , and letting,  $\overset{n}{\alpha}, \overset{n}{\beta} \in \mathbb{R}^+ - (0^+ \cup +\infty)$ , note that,

$$\log[\overset{n}{\beta}](\overset{n}{\alpha}) \notin \overset{n}{\mathcal{F}} \overset{n}{I}_1, \quad (11)$$

which contradicts, Eq. (8a). An instance of this observation is,  $\log_{2.56}(11.4) \notin 0^+$ . Is there a base that can fulfill Eqs. (8)? Understood as a limit, note that,

$$\log[\overset{n}{I}_1](\overset{n}{\alpha}) \in \overset{n}{\mathcal{F}} \overset{n}{I}_1. \quad (12)$$

An instance of this observation is,  $(+\infty)^x = 23.71 \Rightarrow x \in 0^+$ . This suggests the local identification,<sup>2</sup>  $\log(\cdot) \equiv \log[\overset{n}{I}_1](\cdot)$ . Comparing the Eqs. (9) with the limits,

$$\log[+\infty](0^+) = -1^<, \quad \log[+\infty](+\infty) = 1^<, \quad \text{and}, \quad \log[+\infty](1) = 0, \quad (13)$$

implies,

$$-1^< \equiv \overset{n-1}{\mathcal{F}} \overset{n-1}{I}_1, \quad 1^< \equiv \overset{n-1}{I}_1, \quad \text{and}, \quad 0 \equiv \overset{n-1}{I}_0. \quad (14)$$

Whenever the group,  $\mathfrak{g}_n$ , is associated to,  $(\mathbb{R}^+, \times)$ , the open interval,  $(-1, +1)$ , provides the elements for the abelian group,  $\mathfrak{g}_{n-1}$ , associated to the product,  $\overset{n-1}{\times}$ , with group identity,  $\overset{n-1}{I}_0 \equiv 0$ , and inverse,  $\overset{n-1}{\mathcal{F}}(\cdot) \equiv (-1) \times (\cdot)$ . Recalling that,  $\overset{n}{\times}$ , is distributive in,  $\overset{n-1}{\times}$ , completes the similarities of,  $\overset{n-1}{\times}$ , with the conventional sum,  $+$ .

---

<sup>2</sup>An alternative is,  $\log(\cdot) \equiv \log[\overset{n}{\mathcal{F}} \overset{n}{I}_1](\cdot)$ , which modifies by,  $\overset{n-1}{\mathcal{F}}$ , the output.

Twitter thread by @judijasa  
 Title: The logarithmic chain complex  
 Slide Nr. 4/8

The definition of the log action can be extended beyond the transformation of elements defined in Eqs. (8). From Eq. (2), it follows that,

$$\log(\overset{n}{\alpha} \times \overset{n}{\beta}) = \log(\overset{n}{\alpha}) \overset{n-1}{\times} \log(\overset{n}{\beta}). \quad (15)$$

Define the log action on products as,

$$\log(\overset{n}{\times}) = \overset{n-1}{\times}. \quad (16)$$

The Eq. (15) now follows from distributivity of the log action in elements and products, i.e.,

$$\log(\overset{n}{\alpha} \times \overset{n}{\beta}) = \log(\overset{n}{\alpha}) \log(\overset{n}{\times}) \log(\overset{n}{\beta}). \quad (17)$$

Similarly, one can define the log action on the inverse as,

$$\log(\overset{n}{\mathcal{I}}) = \overset{n-1}{\mathcal{I}}. \quad (18)$$

The familiar relation,  $\overset{n}{\alpha} \in (\mathbb{R}^+, \times)$ :

$$\log(1/\overset{n}{\alpha}) = -\log(\overset{n}{\alpha}), \quad (19)$$

motivates the general form,  $n \in \mathbb{Z}$ :

$$\log(\overset{n}{\mathcal{I}} \overset{n}{\alpha}) = \overset{n-1}{\mathcal{I}} \log(\overset{n}{\alpha}). \quad (20)$$

The latter equation also follows from distributivity of the log action on elements and inverse operations, i.e.,

$$\log(\overset{n}{\mathcal{I}} \overset{n}{\alpha}) = \log(\overset{n}{\mathcal{I}}) \log(\overset{n}{\alpha}). \quad (21)$$

Recall from slide Nr. 003, that if,  $\overset{n}{\alpha} \in (\mathbb{R}^+, \times)$ , then,  $\overset{n-1}{\alpha} = \log(\overset{n}{\alpha})$ , is an element of a sum-like group with inverse,  $\overset{n-1}{\mathcal{I}} (\cdot) \equiv (-1) \times (\cdot)$ , then,

$$\log(\overset{n-1}{\mathcal{I}} \overset{n-1}{\alpha}) \equiv \log(-\overset{n-1}{\alpha}). \quad (22)$$

Together with Eq. (20), one obtains,

$$\log(-\overset{n-1}{\alpha}) = \overset{n-2}{\mathcal{I}} \log(\overset{n-1}{\alpha}). \quad (23)$$

This describes the log action on the negative numbers as a particular case. In the next slide we identify the inverse,  $\overset{n-2}{\mathcal{I}}$ .

Twitter thread by @judijasa  
 Title: The logarithmic chain complex  
 Slide Nr. 5/8

The sequence of products defined in Eq. (2) requires a consistent definition for the log action on negative numbers. Such definition is given by Eq. (23) if,  $(\mathbb{R}^+, \times)$ , represents the  $n$ -group<sup>3</sup>. To fully identify Eq. (23) in the present representation reduces to identify the product inverse,  $\overset{n-2}{\mathcal{F}}$ . Comparing the Eqs. (9) and (14) with the limits,

$$\log[+\infty](-1^<) = -\infty, \quad \log[+\infty](+1^<) = 0^-, \quad \text{and}, \quad \log[+\infty](0) = -1, \quad (24)$$

implies,

$$-\infty \equiv \overset{n-2}{\mathcal{F}} \overset{n-2}{I}_1, \quad 0^- \equiv \overset{n-2}{I}_1, \quad \text{and}, \quad -1 \equiv \overset{n-2}{I}_0. \quad (25)$$

The set,  $\mathbb{R}^-$ , provides the elements for the abelian group,  $\mathfrak{g}_{n-2}$ , with associated product,  $\overset{n-2}{\times}$ , group identity,  $-1$ , and inverse,  $\overset{n-2}{\mathcal{F}} \equiv 1/(\cdot)$ . Comparing with Eqs. (10) one obtains that,  $\overset{n-2}{\mathcal{F}} \equiv \overset{n}{\mathcal{F}}$ . The latter identification is not a general property of the sequence of products, it results from the limited description of the representation chosen. In general, the native representation of the inverse is given by,  $n \in \mathbb{Z}$ :<sup>4</sup>

$$\overset{n}{\mathcal{F}}(\cdot) \equiv (\overset{n}{\mathcal{F}} \overset{n+1}{I}_0) \overset{n+1}{\times}(\cdot). \quad (26)$$

Despite,  $\mathbb{R}^-$ , is not closed under the conventional multiplication,  $\times$ , it is closed under the product,  $\overset{n-2}{\times}$ , as defined in Eq. (2). Proof: Using Eq. (8) one proceeds by induction,

$$\begin{aligned} \overset{n-2}{\alpha} \overset{n-2}{\times} \overset{n-2}{\beta} &= \log \left( \log^{-1}(\overset{n-2}{\alpha}) \overset{n-1}{\times} \log^{-1}(\overset{n-2}{\beta}) \right) \\ &= \log(\overset{n-1}{\alpha} \overset{n-1}{\times} \overset{n-1}{\beta}) = \log(\overset{n-1}{\gamma}) = \overset{n-2}{\gamma}. \end{aligned} \quad (27)$$

As explained in more detail in slide Nr. 8, due to limitations in the representation, the groups,  $\mathfrak{g}_n$ , and,  $\mathfrak{g}_{n+4m}$ , where,  $m, n \in \mathbb{Z}$ , are related by an automorphism. Under this representation, it is therefore sufficient to identify four consecutive groups to describe the sequence of groups. After setting,  $\mathfrak{g}_n \equiv (\mathbb{R}^+, \times)$ , we already identified the consecutive groups,  $\mathfrak{g}_{n-1}$ , and,  $\mathfrak{g}_{n-2}$ . In slide Nr. 8 we complete the analysis by identifying,  $\mathfrak{g}_{n-3}$ , but before we shall refine some concepts.

---

<sup>3</sup>The choice of representation for the  $n$ -group constrains the representation of nearby groups.

<sup>4</sup>To test involution of inverse in the native rep, note that,  $\alpha \overset{m}{\times} (\overset{n}{\mathcal{F}} \beta) = (\overset{n}{\mathcal{F}} \alpha) \overset{m}{\times} \beta = \overset{n}{\mathcal{F}}(\alpha \overset{n}{\times} \beta)$ , if,  $m = n + 1$ .

Twitter thread by @judijasa  
 Title: The logarithmic chain complex  
 Slide Nr. 6/8

Define the  $n$ -group's 'absolute value' as,

$$|\cdot|_n = |\cdot|_{n-1} \times^{\frac{n}{n-1}} \mathcal{J}(\cdot), \quad (28)$$

where,  $|\cdot|_0$ , is the conventional absolute value. The instants,

$$|- \frac{0}{\alpha}|_0 = | \frac{0}{\alpha}|_0, \quad |1/\frac{1}{\alpha}|_1 = | \frac{1}{\alpha}|_1, \quad (29)$$

and,

$$|1/\frac{0}{\alpha}|_0 = 1/| \frac{0}{\alpha}|_0, \quad |- \frac{1}{\alpha}|_1 = -| \frac{1}{\alpha}|_1, \quad (30)$$

motivate the general assumptions,<sup>5</sup>

$$| \frac{n \pm 1}{\mathcal{J}} \alpha |_n = \frac{n \pm 1}{\mathcal{J}} | \alpha |_n, \quad \text{and,} \quad | \frac{n}{\mathcal{J}} \alpha |_n = | \alpha |_n. \quad (31)$$

An important property is that,  $|\mathfrak{g}_n|_n$ , is isomorphic to the open interval,  $(\mathbb{I}_0, \mathbb{I}_1)$ , while,  $|\mathfrak{g}_n|_{n+1}$ , is isomorphic to,  $\mathbb{Z}_2$ . The proof of the latter is the following: Any element in,  $\mathfrak{g}_n$ , can be parametrised as,  $\alpha = (\mathcal{J})^\nu | \alpha |_n$ , where,  $(\mathcal{J})^1 = \mathcal{J}$ , and,  $(\mathcal{J})^2(\cdot) = \mathbb{I}_0 \times^{\frac{n}{n-1}} (\cdot)$ . Then,

$$\begin{aligned} | \alpha |_n &= | \alpha |_n \times^{\frac{n+1}{n}} \mathcal{J} \alpha \\ &= | \alpha |_n \times^{\frac{n+1}{n}} \mathcal{J} (\mathcal{J})^\nu | \alpha |_n \\ &= (\mathcal{J})^\nu (| \alpha |_n \times^{\frac{n+1}{n}} \mathcal{J} | \alpha |_n) = (\mathcal{J})^\nu \mathbb{I}_0. \end{aligned} \quad (32)$$

In general,  $k \in \mathbb{Z}^+$ :

$$| \alpha |_{n-k} = | \alpha |_n \times^{\frac{n}{n-1}} \alpha \times^{\frac{n-1}{n-2}} \alpha \times^{\frac{n-2}{n-3}} \dots \times^{\frac{n-k+1}{n-k}} \alpha, \quad (33)$$

and,

$$| \alpha |_{n+k} = | \alpha |_n \times^{\frac{n+1}{n}} \mathcal{J} \alpha \times^{\frac{n+1}{n+2}} \mathcal{J} \alpha \times^{\frac{n+2}{n+3}} \dots \times^{\frac{n+k}{n+k+1}} \mathcal{J} \alpha. \quad (34)$$

---

<sup>5</sup>Despite,  $(\frac{n}{\mathcal{J}} \alpha) \times^{\frac{n}{n-1}} \beta \neq \alpha \times^{\frac{n}{n-1}} (\mathcal{J} \beta)$ , it holds that,  $(\mathcal{J} | \alpha |_{n \pm 1}) \times^{\frac{n}{n-1}} \alpha = | \alpha |_{n \pm 1} \times^{\frac{n}{n-1}} (\mathcal{J} \alpha)$ . Some of these assumptions can be derived from a minimal set, so there is work to do for a more concise presentation.

Twitter thread by @judijasa  
 Title: The logarithmic chain complex  
 Slide Nr. 7/8

Define the proper metric in,  $\mathfrak{g}_n$ , as,

$$g_n(\alpha, \beta) = |\alpha \times \overset{n}{\mathcal{F}} \beta|_n. \quad (35)$$

The metric,  $g_{n+1}$ , distinguishes attributes between elements,  $\overset{n}{\alpha}, \overset{n}{\beta} \in \mathfrak{g}_n$ , that go ‘under the radar’ in the metric,  $g_n$ . These attributes are generated by the group inverse,  $\overset{n}{\mathcal{F}}$ .

Recall the identifications,  $0^+ \equiv \overset{n}{\mathcal{F}} \overset{n}{I}_1$ , and,  $0 \equiv \overset{n-1}{I}_0$ . The instant,  $0^+ \in 0$ , motivates the general assumption,  $n \in \mathbb{Z}$ :

$$\overset{n}{\mathcal{F}} \overset{n}{I}_1 \in \overset{n-1}{I}_0. \quad (36)$$

Moreover, since,  $\overset{n-1}{\mathcal{F}} \overset{n-1}{I}_0 = \overset{n-1}{I}_0$ , then it also holds that,  $\overset{n-1}{\mathcal{F}} \overset{n}{\mathcal{F}} \overset{n}{I}_1 \in \overset{n-1}{I}_0$ . Recalling that,  $\overset{n-1}{\mathcal{F}} \equiv (-1) \times (\cdot)$ , the latter case corresponds to the instant,  $0^- \in 0$ .

Two elements,  $\overset{n}{\alpha}$ , and,  $\overset{n}{\beta}$ , are said to be *infinitesimally close* if,

$$g_n(\overset{n}{\alpha}, \overset{n}{\beta}) = \overset{n+1}{\mathcal{F}} \overset{n+1}{I}_1, \quad (37)$$

and said to have the *same phase* if,

$$g_{n+1}(\overset{n}{\alpha}, \overset{n}{\beta}) = \overset{n+2}{\mathcal{F}} \overset{n+2}{I}_1. \quad (38)$$

If two elements of the same group are infinitesimally close and have the same phase they are said to be equal elements in the group, denoted,  $\overset{n}{\alpha} \overset{n}{=} \overset{n}{\beta}$ . Two elements,  $\alpha, \beta$ , are said to be equal if,  $g_n(\alpha, \beta) = \overset{n+1}{\mathcal{F}} \overset{n+1}{I}_1$ , for all,  $n \in \mathbb{Z}$ .

Away of the identity, being infinitesimally close is sufficient criteria for equality in the group, i.e., if,  $g_n(\overset{n}{\alpha}, \overset{n}{\beta}) = \overset{n+1}{\mathcal{F}} \overset{n+1}{I}_1$ , and,  $\overset{n}{\alpha} \notin \overset{n}{I}_0$ , then,  $\overset{n}{\alpha} \overset{n}{=} \overset{n}{\beta}$ . Proof:  $g_n(\overset{n}{\alpha}, \overset{n}{\beta}) = \overset{n+1}{\mathcal{F}} \overset{n+1}{I}_1$ , implies,  $\overset{n}{\alpha} \times \overset{n}{\mathcal{F}} \overset{n}{\beta} \in \overset{n}{I}_0$ , therefore,  $\overset{n}{\alpha} = \overset{n}{\beta} \times \overset{n}{\gamma}$ ,  $\overset{n}{\gamma} \in \overset{n}{I}_0$ . Note that,  $\overset{n}{\alpha} \notin \overset{n}{I}_0$ , if and only if,  $\overset{n}{\beta} \notin \overset{n}{I}_0$ , otherwise,  $\overset{n}{\alpha} \times \overset{n}{\mathcal{F}} \overset{n}{\beta} \notin \overset{n}{I}_0$ , which is a contradiction. Since,  $\overset{n}{\beta} \notin \overset{n}{I}_0$ , then,  $\overset{n}{\beta} \times \overset{n}{\gamma} \overset{n}{=} \overset{n}{\beta}$ , therefore,  $\overset{n}{\alpha} \overset{n}{=} \overset{n}{\beta}$ . From now on, the equality,  $=$ , in Eqs. (6) and (7) is replaced by,  $\overset{n}{=}$ .

Any element in a group can be reinterpreted as a set of infinitesimally close elements in the group metric. Denote,  $\overset{n}{\beta} \in \overset{n}{\alpha}$ , if the element,  $\overset{n}{\beta}$ , is infinitesimally close to the element,  $\overset{n}{\alpha}$ . For example,  $0^\pm \in 0$ , reads as: the elements,  $0^-$ , and,  $0^+$ , are infinitesimally close to zero, in their proper group metric.

Twitter thread by @judijasa  
 Title: The logarithmic chain complex  
 Slide Nr. 8/8

In analogy to the limits,  $\pm\infty = 1/0^\pm$ , define,

$$\infty = 1/0. \quad (39)$$

We are no longer in the real line, the element,  $\infty$ , is the point at infinity in the *real projective line*.

Comparing the Eqs. (9) and (25) with the limits,

$$\log[+\infty](-\infty) = +1^>, \quad \log[+\infty](0^-) = -1^>, \quad \text{and}, \quad \log[+\infty](-1) = \infty, \quad (40)$$

implies,

$$+1^> \equiv \mathcal{T}^{\frac{n-3}{n-3}} I_1, \quad -1^> \equiv I_1^{\frac{n-3}{n-3}}, \quad \text{and}, \quad \infty \equiv I_0^{\frac{n-3}{n-3}}. \quad (41)$$

The set,  $\mathbb{R} - (-1, +1)$ , provides the elements for the abelian group,  $\mathfrak{g}_{n-3}$ , with group identity,  $\infty$ , and inverse,  $\mathcal{T}^{\frac{n-3}{n-3}}(\cdot) \equiv (-1) \times (\cdot)$ . As a result of the representation note that,  $\mathcal{T}^{\frac{n-3}{n-3}} \equiv \mathcal{T}^{\frac{n-1}{n-1}}$ . Finally, comparing the Eqs. (9) and (43) with the limits,

$$\log[+\infty](+1^>) = 0^+, \quad \log[+\infty](-1^>) = +\infty, \quad \text{and}, \quad \log[+\infty](\infty) = +1, \quad (42)$$

implies,

$$0^+ \equiv \mathcal{T}^{\frac{n-4}{n-4}} I_1, \quad +\infty \equiv I_1^{\frac{n-4}{n-4}}, \quad \text{and}, \quad +1 \equiv I_0^{\frac{n-4}{n-4}}. \quad (43)$$

Comparing the latter with Eq. (10) it follows that,  $\mathfrak{g}_{n-4}$ , and,  $\mathfrak{g}_n$ , are related by an automorphism. Since,  $\mathfrak{g}_n \equiv (\mathbb{R}^+, \times)$ , and,  $\overset{1}{\times}$ , behaves as the conventional multiplication, then,  $\mathfrak{g}_1$ , and,  $\mathfrak{g}_n$ , are related by an automorphism. This implies that,  $n$ , must be an odd integer.

As a homework I suggest to study the relation between the sequence of groups,  $\mathfrak{g}_n, \mathfrak{g}_{n+1}, \dots$ , and the formal concept of a *chain complex*.

I guess for a “Twitter thread” this is enough. A development of these notes may soon appear in the website,

<https://judijasa.github.io/>
